Multiple Sclerosis and Related Disorders, Volume 122 (Handbook of Clinical Neurology) From Elsevier

Multiple Sclerosis (MS) is generally understood to be an inflammatory autoimmune disease of the central nervous system. While we still are not certain of the root cause of MS, research results suggest that unknown environmental factors and the presence of specific genes seem the most probable targets. MS causes an inflammatory response in the central nervous system leading to neurodegeneration, oligodendrocyte death, axonal damage, and gliosis. Over the past five years ongoing research has greatly expanded our understanding of the pathogenesis of MS, detailed insight into the epidemiology and genetic factors related to MS, the introduction of new technologies and tests to better diagnose and predict the future course of the disease and the introduction of new treatments targeting MS. This collection of review chapters provides a comprehensive reference into the science and clinical applications of the latest Multiple Sclerosis research and will be a valuable resource for the neuroscience research community and the clinical neurology community of researchers and practitioners.

- A comprehensive tutorial reference detailing our current foundational understanding of Multiple Sclerosis
- Includes chapters on key topics including the genetics of MS, MRI imaging and MS, and the latest treatment options
- Each chapter is translational and focuses on current research and impact on diagnosis and treatment options
